Abstract
Purpose This study examines the extent to which in adolescent positive mental well-being and depressive symptoms vary across ethnic groups, and prospectively examines whether social support is protective against low/poor well-being and depression.
Methods A longitudinal survey of 2426 adolescent from the Olympic Regeneration in East London study measured well-being and depressive symptoms at baseline at ages 11–12 and at follow-up two years later at ages 13–14. Social support was assessed at ages 11–12 years by the Multidimensional Scale of Perceived Social Support, by the level of parental support for school, by the frequency of family activities and by friendship choices. Ethnic differences in well-being and depression in Bangladeshis

estimated adjusted stepwise for socio-demographic factors and domains of social support.
Results Black African and Bangladeshi adolescents scored significantly higher for well-being than their White UK counterparts. There were no significant ethnic differences in the prevalence of depressive symptoms. Lower levels of social support were prospectively associated with lower well-being and higher rates of depression in all ethnic groups. Adjustment for multiple domains of social support did not account for ethnic differences in well-being.
Conclusion Bangladeshi and Black African adolescents in East London may have a positive mental health advantage over their White UK counterparts though social support did not fully mediate this difference. Further

Social support is exceptionally important for maintaining good physical and mental health. Overall, it appears that positive social support of high quality can enhance resilience to stress, help protect against developing trauma-related psychopathology, decrease the functional consequences of trauma-induced disorders, such as posttraumatic stress disorder (PTSD), and reduce medical morbidity and mortality (1). However, despite strong evidence demonstrating the beneficial effects of social support on medical and psychological wellbeing, the field of psychiatry has contributed relatively little to developing, testing, and implementing effective evidence-based interventions aimed at increasing social support for patients and at-risk populations. In this review article, we aim to summarize key studies on social support in the context of resilience to stress and explore possible brain mechanisms mediating social support's positive influence on mental health outcomes (2). We will begin with a brief overview of the neurochemistry of the stress response and resilience to stress. Within this framework, we will then review the emerging literature on the neurobiology and the behavioral mediators of social support. Next, we will review studies that have investigated the effects of social support on medical illness, and finally, conclude with a discussion on social support's clinical significance for psychiatry (3).
